

Ape-Mod-X Online Game description

I've just checked over and updated this a bit... I hope it makes sense and helps..

Account Setup

Users begin by creating an account.

Upon the website establishing that they have the qualifying NFT to play one of these games, users must make an account to log into.

This account is based on their wallet address but also requires them to create a username and possibly to choose a profile image. This profile image could/should be the NFT that's qualified their admission if possible?. If they have multiple qualifying options, they could pick one. I think this gives the NFTs slightly more utility as users can show off their favourite alongside their high score on the leaderboard.

Then they must choose a Username. We could state that in order to win prizes on the leaderboard, users must register a @X name as their username to be notified on prize wins. They'd show this by including the @ in their username, e.g. @Goodebags. If they'd rather stay anonymous and not be eligible to win prizes, they could just register their user name as Goodebags.

Gameplay fundamentals

In a real life physical Ape-Mod-X deck there are 50 different cards/characters and in the real life card game, up to 5 players could split one deck to have 10 cards each, play against each other and win by getting all of the cards.

We've now abandoned the idea of NFT holders playing against each other so all interactions in this online game will be solely between 1 NFT holder and a computer opponent.

The Ape-Mod-X online game was originally meant to represent a shortened 2 player version of the Ape-Mod-X card game in which one user plays against one computer opponent and they each start the game with 10 random (obviously different) cards from the 50 in the deck.

I had originally thought the game should be based on just the 'Couture' Ape-Mod-X series (the yellow ones), but I now think we should also incorporate the 'Mutants' and 'Mecha' Ape-Mod-X series into this one online game as it advertises the other 2 collections/decks, whets peoples appetites for them and demonstrates that the decks work well when played together :)

So now, users would be given 10 cards at random from the total 150 cards mixed from the 3 decks. This is a slight change from my original plan, but I like this idea a lot. What do you think?

If a user wins a 10 card game against one computer opponent, they get 1 point (or maybe 1000 points as it sounds better!).

If they win, they'll be offered a choice to play again immediately (it could time out in 60 seconds), and they could then add more points to their score with more wins. When they eventually lose (or give up), their total score accumulated goes on a score board with their created username and their profile image.

As players have not paid to play, I can reward them with crypto and NFT prizes from time to time without gambling implications.

An option within the game could (and on reflection, I think should) be that a user can opt to play against multiple computer players (up to 4 so each player can still have 10 cards) at once so could win more 'points' in one visit (but statistically have less chance of winning). I think it could mix up the gameplay a little. What do you think? This way, they could win up to 4(000) points by beating 4 computer opponents at once.

Game presentation

The online game could be set out with an oval wooden 'poker' table in front of the user and as many different ape character opponents placed around the table as the user has opted to play against.

The user would be represented with their username in a box next to their stack of cards face down. The (up to four) computer opponents could be represented by a box saying Player 2 (or 3, 4 or 5). I don't think it matters so long as they're spaced around the table? What do you think?

At the very start of the game, the computer will visually scroll through the players and choose one at random to start the game. **If a player wins the whole game they automatically start the next game first.**

Both the player and computer player(s) start by being given 10 cards each, face down in a pack. Their deck could be demonstrated by showing a card shaped box with an Ape-Mod-X card back and a number on/adjacent to it saying how many are in that stack.

The game starts with each players' (remaining card) indicator on 10 and when the user clicks start, the game decides who will be first player by random (unless this is a follow on game in which case the human starts).

The game decides which player will start and when it does, and the user clicks continue again (with a time out to make them after 10 seconds), all players' remaining card indicators immediately drop to 9 and the user's top card is flipped upwards, revealing the card face.

If it's the human user's go, they choose/click on the trait on their card that they want (usually the one that has the highest value, but this can't be automated as there might be 2 traits with same value to choose from) and then the other player's top cards spin around to reveal all of the card faces. The computer instantly detects if any of the other computer players have a higher value (when their XTRA trait is added on) on their card.

Whichever card won the round gets highlighted, then moves to the middle of the screen to have it's little animation played. The winning player gets all the won cards added onto the bottom of their remaining card stack and the game goes onto the next round with the winning player starting the next round.

If it's one of the computer players to go first, the gameplay should be automatic as the human user can't do anything to affect the gameplay and would reply to the leading player's call with their value for that trait + the value of the XTRA trait on that card added on (if any).

When it's a computer player to go first,

The game detects if they've got the best score on the table and gives the cards and the next go to the winner.

The only time a human makes a choice is when it's their go, and that's just to choose what trait they think is best. All the other gameplay should be automatic and I think it should be presented in stages that have a 'Continue' box pop up in between them - probably with a timeout that takes them to the next automated bit after 10 or so seconds.

This box showing the users' decks of cards and the number (stating how many are there) should, I think, be smaller and the main card flipped and in play should take up more room next to it on the screen.

I'll make a diagram to try and visualise all of this (these are in the G drive – the 2 tables with cards on)

When the system issues the random 10 cards to each user, it would immediately know whether these cards are Couture, Mutants or Mecha before they're played, so if we were to display the back

of an Ape-Mod-X card as the indicator for how many cards a user has left and of what the top card is about to be, it will should show whether that card is about to be a Couture, Mutants or Mecha card by showing the correct card back (yellow, green or grey).

When each round starts, the user can see whether both their opponents' card in play and their next top card are Couture, Mutants or Mecha cards by what card back is shown for each and can also see how many cards each other player has left.

If it's the human user's turn to call, their top card is flipped to face up for them to see and for each of their computer opponents, the human can now see a small deck of card backs with a number showing how many cards are in the deck (and what series the next top card comes from) and also the back of the other players' current card in play.

When the human user clicks on the trait category box on the face of the card flipped up in front of them with the highest numerical value, the computer player(s) top card(s) are immediately flipped around revealing their card faces.

The game then highlights the chosen trait category on everyone's cards and also highlights the 'XTRA' trait category box on their cards, signifying that that score is to be added on, and then something like a star with a number in it 'pings' over the winning players card to show that their score was the highest and they've won the round.

Note:

In the Ape-Mod-X game, not The Bee's Knees, all players except the caller (the player that goes first and nominates the trait) get to add on the value (if any) of their XTRA trait to the value of the trait chosen by the caller.

The cards from that round are stacked at random 'underneath' the winning player's deck and the number next to each players deck goes up or down to show how many cards they now have.

After each round, the human user is immediately automatically presented with their next card's face.

They then click a 'Next Round' button to start the next round (and there can be a countdown timer that immediately takes them to the next round after (maybe?) 10 or 20 seconds).

When it's a computer players turn to start a round, after the human player has clicked 'Next Round' the computer player's top card flips over first (and for a moment, is shown larger in the middle of the table, before returning to being in front of them), everyone's current card flips over and the trait category that was chosen highlights on everyone's now visible card faces (along with the XTRA trait box too if applicable) and a number next to it says each player's total score.

The game immediately identifies who has won, pings another star and the round's winning cards are placed underneath the winning player deck.

If two or more players tie scores in a round, as per the card game rules, everybody's cards are frozen (the tying players and any losers) and then just those tying players go again with the same player picking the trait category and the winner winds all of the cards

Ultimately, both of the games are 100% luck based and there's very little players can do to affect the gameplay as all they ever have to do is choose the highest scoring trait on their card.
